Problem
Record Files

Database Management Systems

Introduction
Client / Server
SQL

3 / 29

Problem

- store and process large amounts of data effectively
- add new data
- change existing data
- delete data
- query data: planned - ad hoc
- **CRUD**: create - read - update - delete

4 / 29

Data

- ▶ **persistent** data: data that must be stored due to the nature of the information
- ▶ temporary data
- ▶ output data: data that can be derived from persistent data (query results, reports, etc.)
- ▶ input data: unprocessed data that just entered the system

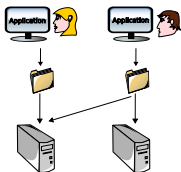

5 / 29

Example: University student data

- ▶ Student Affairs: student name, number, department, courses taken, internships, ...
- ▶ common data: student name, number, department, ...
- ▶ Library: student name, number, department, books lent, ...
- ▶ application specific data: courses, internships, books, ...

6 / 29

Record Files

- ▶ every application has its own data
- ▶ every application keeps its data in the files that it manages itself

7 / 29

Redundancy

- ▶ same data kept in multiple places
- ▶ waste of disk space

example

- ▶ names, numbers and departments of students are kept both in Student Affairs and in the Library

8 / 29

Inconsistency

- ▶ multiple copies of the same data can become different

example

- ▶ the name of the same student can be recorded as "Victoria Adams" in Student Affairs and as "Victoria Beckham" in the Library

9 / 29

Integrity

- ▶ it is difficult to keep the data correct

example

- ▶ "Control and Computer Engineering" department is closed but the department data of its students remains the same

10 / 29

Duplicated Work

- ▶ a lot of work must be duplicated for every new application

example

- ▶ a new application will be developed for the Scholarship Office

11 / 29

Policy Gaps

- ▶ no standards in the applications of the institution
- ▶ different paradigms, methods, programming languages
- ▶ data transfer between applications
- ▶ each department considers only its own requirements

12 / 29

Security

- ▶ hard to define detailed security permissions
- ▶ security depends only on the operating system

13 / 29

Data Dependence

- ▶ **data dependence**: application code depends on the organization of the data and the access method
- ▶ hard to make changes in the code

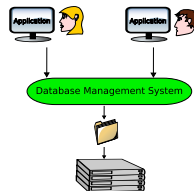

14 / 29

Data Dependence Example

- ▶ student number is a string in Student Affairs but a number in the Library
- ▶ Student Affairs application keeps a B-tree index on the student number
- ▶ B-tree search algorithms are used for queries
- ▶ what if we decide to switch to a hashed index?

15 / 29

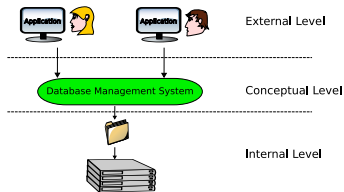

Database Management Systems

- ▶ data is kept in a shared system
- ▶ applications access data over a common interface

16 / 29

ANSI/SPARC Architecture

17 / 29

External Level

- ▶ external level from the end user's perspective:
- ▶ data needed by that end user
- ▶ interface of the application
- ▶ external level from the application programmer's perspective:
- ▶ programming language
- ▶ database extensions to this language: **data sublanguage**

18 / 29

Conceptual Level

- ▶ conceptual level: the entire data
- ▶ where data independence is achieved
- ▶ **catalogue:** definitions that describe the data
- ▶ databases
- ▶ data types, integrity constraints
- ▶ users, privileges, security constraints

19 / 29

Internal Level

- ▶ internal level: implementation details
- ▶ how the data is represented
- ▶ files, records
- ▶ how the data is accessed
- ▶ pointers, indexes, B-trees

20 / 29

Conversions

- ▶ conversions between levels for data independence

example: conceptual - external

- ▶ present the student number as a string to the Student Affairs application, and as a number to the Library application

example: conceptual - internal

- ▶ generate an index on the student number

21 / 29

Administrator Roles

- ▶ data administrator: makes the decisions
 - ▶ which data will be stored?
 - ▶ who can access which data?
- ▶ database administrator: applies the decisions
 - ▶ defines the conceptual - external/internal conversions
 - ▶ adjusts system performance
 - ▶ guarantees system availability

22 / 29

DBMS Functions

- ▶ data definition language
- ▶ data manipulation language
- ▶ checking data manipulation requests for security constraints
- ▶ checking data manipulation requests for integrity constraints
- ▶ processing simultaneous requests properly
- ▶ performance

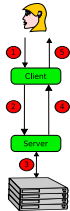

23 / 29

Client / Server Architecture

- ▶ **server**: provides the DBMS functions
- ▶ **client**: provides the interaction between the user and the server
 - ▶ vendor supplied tools (query processors, report generators, ...)
 - ▶ applications developed by application programmers

24 / 29

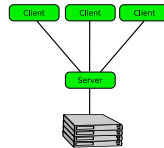

Architecture

- ▶ client and server can be on the same computer or on different computers

25 / 29

Multiple Clients / Single Server

- ▶ many clients can connect to a single server
- ▶ server is a bottleneck
- ▶ replication

26 / 29

SQL

- ▶ **Structured Query Language**
- ▶ data definition language
- ▶ data manipulation language
- ▶ interaction with general purpose programming languages
- ▶ started by IBM in the 1970s
- ▶ standards: 1992, 1999, 2003

27 / 29

SQL Products

- ▶ Oracle, IBM DB2, MS-SQL, ...
- ▶ open source: PostgreSQL, MySQL, ...
- ▶ embedded: SQLite, ...
